Simple Regression

1. Suppose we specify the population regression model to be

$$
y_{i}=a+b x_{i}+u_{i}
$$

Where $x_{i}$ is a composite price index based on 500 common stocks and $Y_{i}$ is aggregate investment during the next period. We wish to estimate the model parameters from twenty observations. The following information has been calculated:
$\bar{y}=\frac{1}{\mathrm{n}} \sum \mathrm{y}_{\mathrm{i}}=88.915 \quad, \quad \overline{\mathrm{x}}=\frac{1}{\mathrm{n}} \sum \mathrm{x}_{\mathrm{i}}=688.92 \quad, \quad \mathrm{~s}_{\mathrm{y}}^{2}=\frac{1}{\mathrm{n}-1} \sum\left(\mathrm{y}_{\mathrm{i}}-\overline{\mathrm{y}}\right)^{2}=11,485 / 19$

As well as the additional calculations;
$\mathrm{s}_{\mathrm{x}}^{2}=\frac{1}{\mathrm{n}-1} \sum\left(\mathrm{x}_{\mathrm{i}}-\overline{\mathrm{x}}\right)^{2}=628713 / 19$
$s_{x y}=\frac{1}{n-1} \sum\left(x_{i}-\bar{x}\right)\left(y_{i}-\bar{y}\right)=77685 / 19$
a. What are the least squares estimates of the intercept and slope for this model?
b. The following calculations have also been made:

$$
\begin{aligned}
& \sum\left(\mathrm{y}_{\mathrm{i}}-\hat{\mathrm{y}}_{\mathrm{i}}\right)^{2}=1901 \\
& \sum\left(\hat{\mathrm{y}}_{\mathrm{i}}-\overline{\mathrm{y}}\right)^{2}=9584
\end{aligned}
$$

What is your estimate of $\operatorname{Var}\left(u_{i}\right)$ ?
c. At the $5 \%$ level of significance would you accept or reject the null hypothesis that the slope coefficient is no different from zero?
d. At the 5\% level of significance test

$$
\mathrm{H}_{0}: \mathrm{a}=0
$$

$$
\mathrm{H}_{1}: \mathrm{a} \neq 0
$$
